

ReadyToSubmit

Catch document problems before a scholarship application is submitted.

Draft proposal for The Code Blooded

AWS First Commit Hackathon | 17-20 September 2026

Prepared 17 September 2026 | Working product name

Problem statement

Students applying for scholarships must assemble information from several documents and follow scheme-specific requirements. Differences in names, missing attachments and unreadable fields can go unnoticed until verification. Students need a clear way to check their application packet before submission and understand which issues need attention.

Proposed challenge: Build a student-facing application that checks a document packet against one verified scholarship checklist, flags possible inconsistencies with visible evidence, and helps the student review and resolve them before applying through the official portal.

Evidence and limits

A December 2025 Chandernagore College notice warns SVMCM applicants that spelling, initials or name-order differences between bank records and applications can cause verification failure.

Buddy4Study also documents identity-detail mismatches as a cause of failed verification. These sources establish a concrete problem, but do not establish its national prevalence or the number of scholarships lost. [1, 2]

Who it serves

Primary user: A college student preparing a scholarship application.

Secondary user: A college scholarship coordinator helping students review documents.

Desired outcome: Fewer avoidable document issues and less time spent manually comparing fields. This outcome must be measured in a pilot.

Product promise

"Show me what needs checking, where the evidence is, and what to do next." The app provides a preparation check. It does not authenticate documents, verify a bank account, decide eligibility or guarantee acceptance.

Existing solutions

The opportunity is a focused review workflow; uniqueness remains a hypothesis.

Existing solution	Documented capability	Gap or boundary relevant to this proposal
Buddy4Study identity verification [2]	Links Aadhaar and NSP OTR; detects identity mismatches during verification.	Strong overlap on identity checking. The reviewed page does not demonstrate a student-controlled, highlighted review across a full uploaded application packet. Validate before claiming a product gap.
BuddyBot [3]	Answers questions about registration, results, application status and required documents.	The public interface reviewed does not demonstrate cross-document comparisons with highlighted source evidence. Absence from that page is not proof the feature is unavailable elsewhere.
myScheme [4]	Government-scheme discovery, eligibility-based search and application guidance.	Its stated focus is discovery and guidance. The reviewed overview does not describe reviewing a student's uploaded scholarship documents as a packet.
AI Scholar Hunt / GitHub [5]	Repository describes scholarship discovery, eligibility checks, essay review and application-support tools.	Adjacent project, with functionality described by its author rather than independently tested. Reviewed documentation does not establish the proposed evidence-linked packet review.
Amazon Textract [6]	Extracts text, forms and tables from documents.	An enabling component: an application still needs scheme rules, cross-document comparisons, uncertainty handling and a student-facing correction workflow.

Differentiation to validate

Combine a versioned scholarship checklist, comparisons across documents, highlighted evidence, explicit uncertainty and rechecking after replacement. The proposed advantage is this complete workflow for a narrow student use case, rather than a claim to have invented document checking.

Research scope: Public product pages and repository descriptions reviewed on 17 September 2026. No exhaustive market audit or authenticated competitor testing was performed. "Not documented" must not be presented as "does not exist".

The weekend MVP

One scholarship. Three document types. Four useful checks.

Select one scholarship after reviewing its current official requirements. SVMCM is a candidate because the problem evidence refers to it; final checklist and document types must be confirmed before implementation. For planning, use an application summary, bank document and academic record as illustrative document types.

Check	Expected behaviour
Required attachments	Compare supplied files against the selected, source-linked checklist. Flag missing documents.
Name consistency	Compare extracted names across relevant documents. Flag differences for review; do not assume initials or transliterations mean different people.
Required fields	Flag missing or unreadable fields required by the chosen checklist. Let the student inspect and correct extraction.
File constraints	Check file size and type only against verified portal requirements. Do not invent universal limits.

Core user journey

Choose scholarship; upload files; confirm extracted fields; inspect findings and evidence; replace files; recheck; download a review summary.

Illustrative finding: "Your application says Ananya Sharma; your bank document says Ananya S. Sharma. Review this difference." Show both original snippets and a relevant source rule, if one applies. Label unsupported concerns as manual-review suggestions.

Scope boundaries

Use English printed documents and synthetic samples for the public demo. Exclude automatic submission, government API integration, fraud detection, scholarship discovery, acceptance predictions and automatic editing of official documents. Additional languages and schemes belong after the hackathon.

AWS implementation proposal

Amplify: host the web interface. **S3:** private document storage with short-lived upload links. **Lambda + API Gateway:** orchestration and explicit comparison rules. **Textextract:** extract text and positions. **Bedrock:** explain findings using supplied evidence. **DynamoDB:** job status and checklist versions. Add authentication for private user access.

Keep pass/fail checks in code; use the model for explanations, with manual-review fallbacks. Textextract currently excludes Hindi from its supported languages. Confirm account access, region and model availability on day one. [6, 7]

Build roadmap

Aim for a working deployed flow early, then improve evidence and reliability.

When	Work	Exit criterion
17 Sep / Define + prove	Review one official checklist; ask 3-5 students or one coordinator about recurring errors. Create a fresh repo and synthetic samples. Test AWS extraction and deployment access.	One documented checklist, confirmed scope and one sample extracted successfully.
18 Sep / Complete the flow	Build upload, field confirmation, four checks, findings view and replacement/recheck. Deploy a thin end-to-end version.	A flawed synthetic packet produces evidence-linked findings on a working URL.
19 Sep / Test + refine	Add uncertainty handling, document highlights and source links. Test clean, flawed and unreadable samples; review with a student. Improve layout and access controls.	Results recorded on the test set; no silent success on failed extraction.
20 Sep / Package + submit	Freeze features, verify the live URL, record the demo and finish README/write-up. Submit early once the form opens; retain time for corrections.	Public repo, video up to 3 minutes, write-up and working AWS demonstration.

Timing note: The official schedule lists 20 September as submission day, but says exact hours are still being finalised. Confirm the published deadline and timezone; do not assume midnight. [8, 9]

Suggested ownership

For a solo build, implement in roadmap order. With teammates, split frontend/evidence display, backend/AWS, and checklist/testing/demo. All roles share one agreed example packet and output format.

Acceptance targets - proposed, not achieved

Prepare 20 synthetic packets: 5 clean, 10 with known issues and 5 unreadable or ambiguous. Target at least 90% detection of seeded missing-file and format violations, zero false blockers on clean packets, and a visible manual-review state for every extraction failure. Report name-mismatch results separately; never hide uncertainty in a single score.

After the hackathon

Week 1: Validate usefulness with consenting students using redacted samples and coordinator feedback.

Weeks 2-3: Improve extraction, source freshness and privacy controls. **Weeks 4-6:** Add a second scheme and assess another language only after the first workflow performs reliably.

Validation and references

Make the evidence, limitations and next decisions easy to inspect.

Main risks and responses

Wrong or stale rules: Store source URL, date checked and checklist version; review manually before release.

OCR or name ambiguity: Show original evidence and request confirmation; do not claim document authenticity.

Private documents: Use synthetic demo data, private storage, scoped access and an explicit retention/deletion policy.

Build time: Prioritise upload, checks and evidence display. If Bedrock access blocks progress, keep templated explanations and disclose this.

Unproven demand: Ask users about their last application and actual errors before extending the product.

Three-minute demo plan

0:00-0:25: Student problem and evidence. **0:25-1:20:** Upload a synthetic packet and inspect highlighted findings. **1:20-2:05:** Replace a file, recheck, and show one ambiguous case. **2:05-2:35:** Demonstrate actual AWS usage. **2:35-3:00:** Explain measured test results and limits. Do not present proposed targets as achieved results.
